

The water cycle describes the continuous movement of water between the oceans, the atmosphere, and the land. The sun drives evaporation from oceans and lakes, water vapor cools and condenses into clouds, and it eventually falls back down as precipitation before collecting in rivers and groundwater and flowing back to the sea.

Photosynthesis is the process plants use to turn sunlight, water, and carbon dioxide into glucose and oxygen. It happens mainly inside chloroplasts, using a green pigment called chlorophyll to capture light energy, and it is the foundation of almost every food chain on Earth.

The Solar System consists of the Sun and everything bound to it by gravity, including eight planets, their moons, and countless asteroids and comets. The four inner planets are small and rocky, while the four outer planets are much larger and made mostly of gas and ice.

The human digestive system breaks food down into nutrients the body can absorb. Digestion starts in the mouth with chewing and saliva, continues in the stomach where acid and enzymes break food down further, and finishes in the small and large intestines, where nutrients and water are absorbed.

Plate tectonics explains how Earth's outer shell is broken into large plates that slowly move over the layer beneath them. Where plates collide, push apart, or slide past each other, they cause earthquakes, volcanic activity, and the formation of mountain ranges over millions of years.
